ChatGPT said:

Let's use just **one real-life example: finding your name on a list.** 😊

Imagine a list containing 100 names. You check names one by one.

🟤 1. Big O — O (Upper limit)

Your name is at the end. You might need to check all 100 names.

Think: Maximum work limit.

🟢 2. Big Omega — Ω (Lower limit)

Your name is at the beginning. You need only one check.

Think: Minimum work limit.

🟡 3. Big Theta — Θ (Tight limit)

Now imagine you must read every name on the list to count how many names there are.

If there are 100 names, you read 100.
If there are 1,000 names, you read 1,000.

The work grows directly with the number of names.

Think: Work grows at the same rate as the list size.

🧠 Remember these three words!

Symbol	Remember
O	Upper
Ω	Lower
Θ	Tight

The easiest way to understand the difference:

- **O:** How high can the work grow?
- **Ω:** How low can the work grow?
- **Θ:** What growth rate describes the work tightly?

That's it! You don't need to memorize anything else yet.

If you want, I can:

- ↳ Explain examples of Big O, Big Omega, and Big Theta with different algorithms
- ↳ Describe the importance of tight bounds for algorithm analysis
- ↳ Provide a step-by-step example to determine Big O, Omega, and Theta for a given function
