ChatGPT said:

Let's use a much simpler example. Imagine filling a water bottle.

- **Big O:** Filling takes at most 10 minutes.
- **Big Ω (Omega):** Filling takes at least 2 minutes.
- **Big Θ (Theta):** Filling always takes roughly the same amount of time as the bottle size increases.

Think of it this way

Imagine you know:

- Fastest: 2 minutes
- Slowest: 10 minutes

Can you calculate Theta from these two numbers? No! You need to know how the filling time grows as the bottle gets bigger.

The easiest way to remember

Symbol	Meaning
O	Upper limit
Ω	Lower limit
Θ	Upper and lower limits have the same growth rate

Theta is not the average between O and Ω. It means both limits describe the same growth rate.

If you want, I can:

- ↳ Explain Big O, Omega, Theta with more real-world analogies
- ↳ Show how to determine Theta with a specific numerical example
- ↳ Explain differences between Big O, Omega, Theta using a graph or table
